

A photograph of a traditional Japanese street scene. The street is paved and lined with dark wooden buildings. On the right, there is a stone wall with green plants. In the background, a lush green hill is visible under a blue sky with light clouds. The text "Multisensory and sequential experiences in urban and architectural spaces" is overlaid in white.

Multisensory and sequential experiences in urban and architectural spaces

Dr. Ryuzo Ohno
Professor Emeritus,
Tokyo Institute of Technology

Modern versus traditional streetscapes

Saitama New Urban Center

Narai-juku, preserved Edo period post town

Environmental design concepts incorporating nonvisual senses

- Vision – Landscape
- Hearing – Soundscape

Proposed by **R. Murray Schafer** in order to rethink the primacy of vision in modern Western civilization and try to revive auditory culture

- Olfaction – Smellscape

Proposed by **J. D. Porteous** in order to try to restore the rich nonvisual experiences being lost today from the urban environment

The bustling soundscape of the Ameyoko shopping district in Tokyo

The enticing smell at a popular drinking spot under the railroad tracks in Tokyo

Role of touch and kinesthetic sensations

The sudden change underfoot from smooth asphalt to bumpy cobblestones draws pedestrians' attention to their surroundings (Helsinki, Finland)

Even today, my memories of walking up and down these steps are strongly tied to my impressions of the city (Chongqing, China, in the 1980s.)

Experimental study:

Place identification through kinesthetic experience*

Goal: to examine how the kinesthetic experience of walking a road affects the memory of places along the route

Method

31 participants walked along three routes while trying to remember six specified locations

Three experimental routes

Route I: Sloped, Non-grid,

Route II: Flat, Grid

Route III: Flat, Non-grid

Participants later completed three different recall experiments

Ohno, R., Nakayasu, M., & Soeda, M. (2002). Kinesthetic sequential memory as a factor of place identification. *Journal of Architecture and Planning (Transactions of AIJ)*, 67(560), 173-178.

Three recall experiments

1. Randomized Photo

12 photographs in random order showing 6 locations participants had been asked to remember and 6 other locations (fragmentary visual cues)

2. CG Animation

CG animation showing only the road surface geometry of the experimental route on a PC display.
(kinesthetic cues)

3. Sequential Scene Photo

Photos taken every 4 meters along the route
(visual and kinesthetic cues)

Result and analysis

Type classification by memory cues

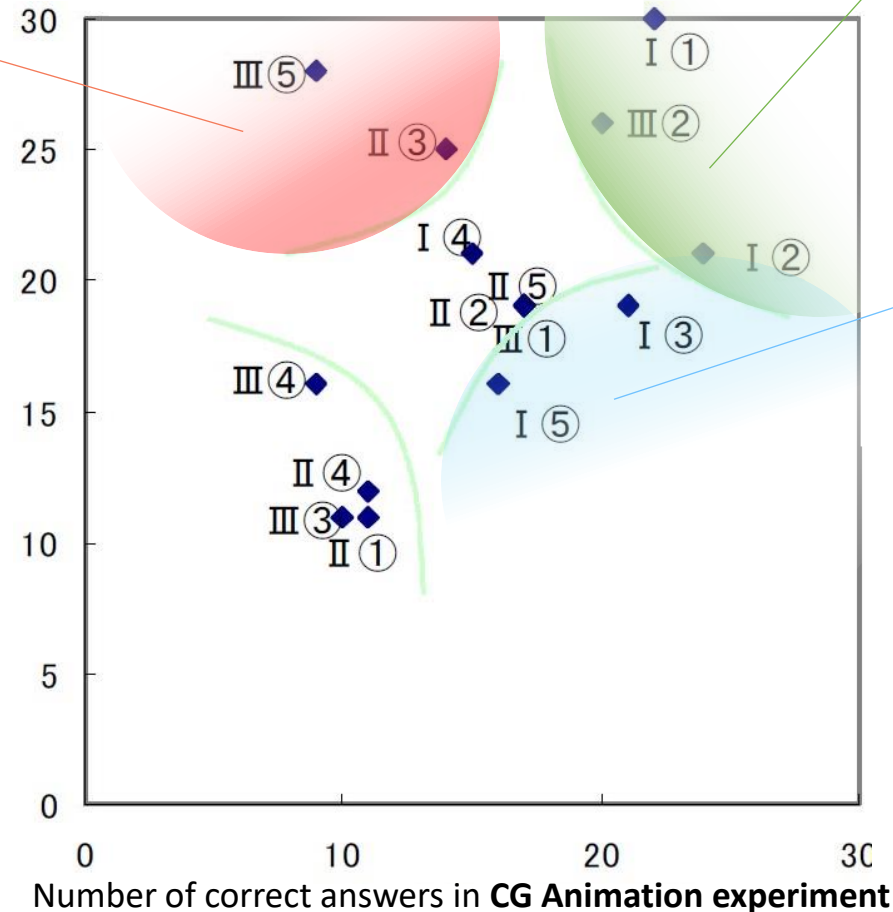

(3) Visual element memory type:

Rich in visual cues

Grid/flat

Number of correct answers
in **Randomized Photo** experiment

(1) Visual element + kinesthetic memory type:

Rich in both visual and kinesthetic cues

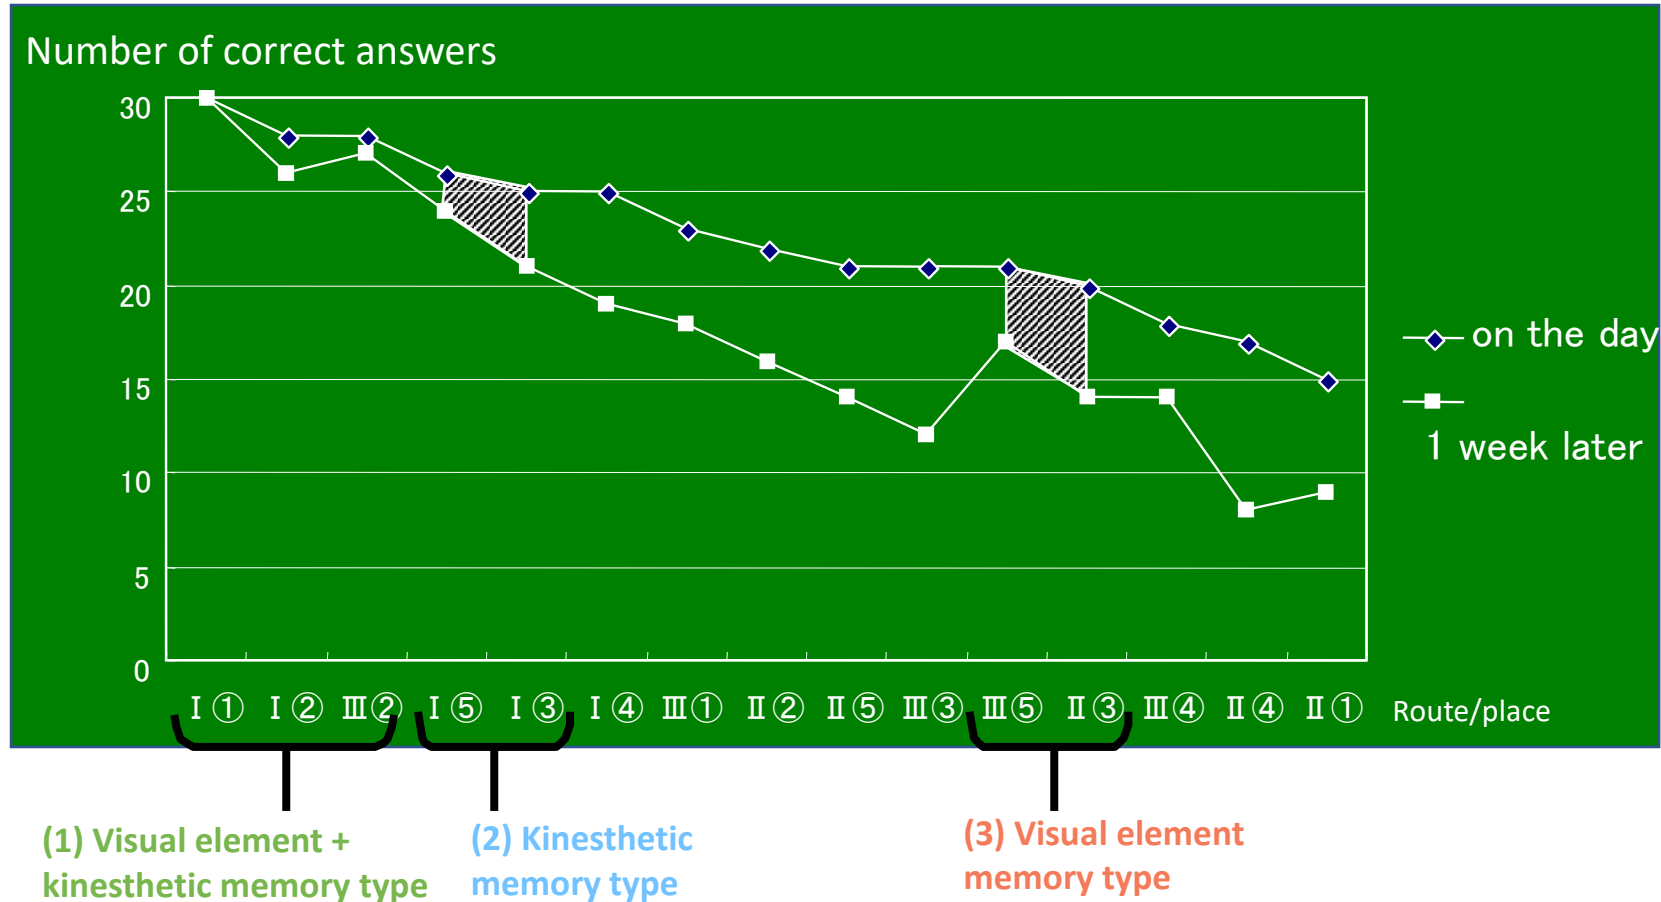

(2) Kinesthetic memory type:

Rich in kinesthetic cues

Non-grid/sloped

Effect of kinesthetic memory on place identification

Results of Sequential Photo experiment

Results and analysis

Number of correct answers declined in order of type 1 (visual + kinesthetic cues) → type 2 (kinesthetic cues) → type 3 (visual cues)

Correct responses declined more sharply over time for type 3 (visual cues) than for type 2 (kinesthetic cues)

Conclusion

Recall is stronger, and also lasts longer, for places remembered with the aid of kinesthetic cues

Introduction to ambient vision

Focal vision

Peripheral vision

Within fixed field of view

Ambient vision

All directions around the perceiver

Encompasses a time range that includes looking around and moving about

Ambient vision

The two visual systems

	Focal vision	Ambient vision
Neural pathways	Via thalamus / visual cortex (cerebrum)	Via the superior colliculus (midbrain)
Perceiver's attitude	Conscious / attentional	Unconscious / subliminal
Behavioral function	Detection / recognition of objects	Arousal of attention Body orientation / locomotion
Nature of information processing	Perceptual selection Cognitive	Perceptual integration Intuitive
Outcome	Understanding	Global impression / feeling

Two models of how we construct our visual world

*A homogeneous visual field with brightness but no area of stimulation

Quantitative description of the global impression of a place

From the above discussion:

The impression evoked by a place can be described in terms of its environmental surfaces

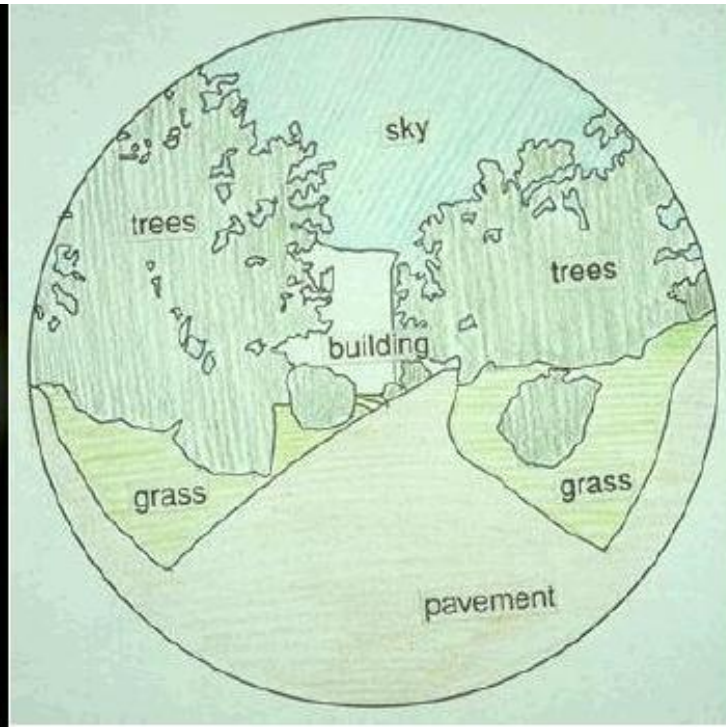

Hypotheses:

- Basic units of information in ambient vision = the components into which the environmental surface can be divided according to fundamental differences in meaning
- Global impression of a place = makeup of these different components within the whole

Computer program for measuring ambient visual information

Photo taken with a fisheye lens

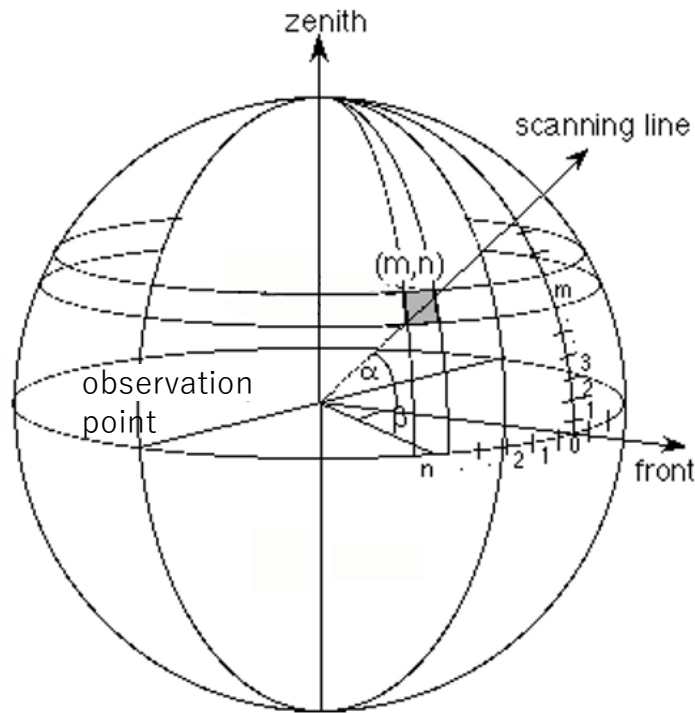

Manual breakdown of components

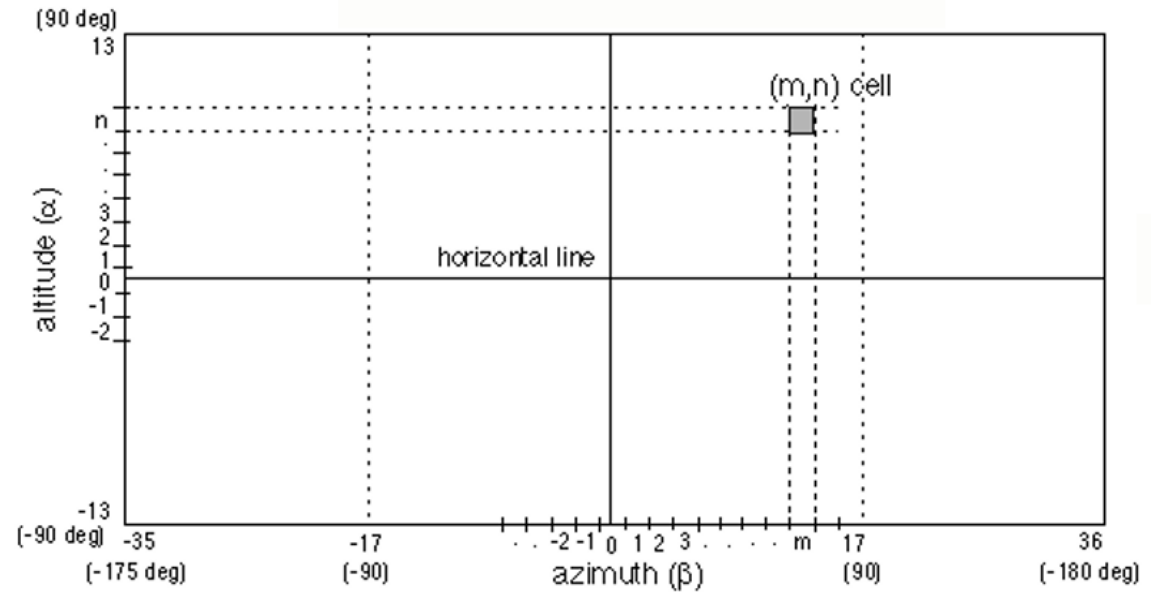

Computer breakdown of the same scene

The program: basic principles

Projection sphere

Results matrix

- Scanning lines (lines of sight) are emitted from an observation point until they reach the environmental surface
- The program determines the component type and distance of the surface
- The results are displayed in matrix form

The program in action

User prepares (a) terrain data, (b) site plan data, and (c) tree data and inputs the position of the observation point

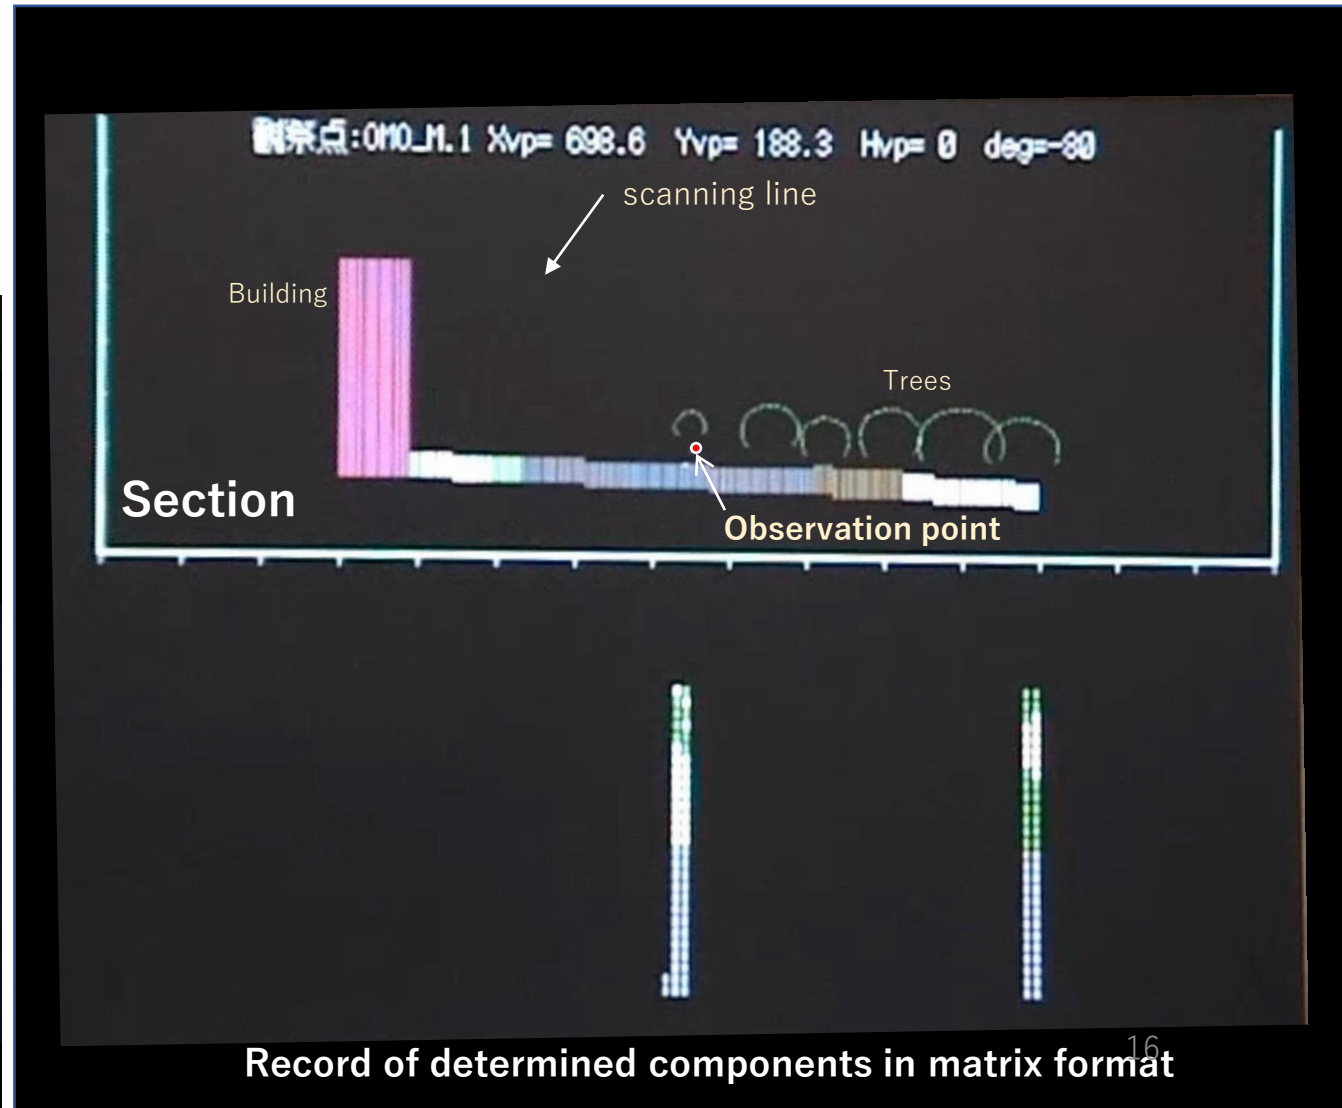

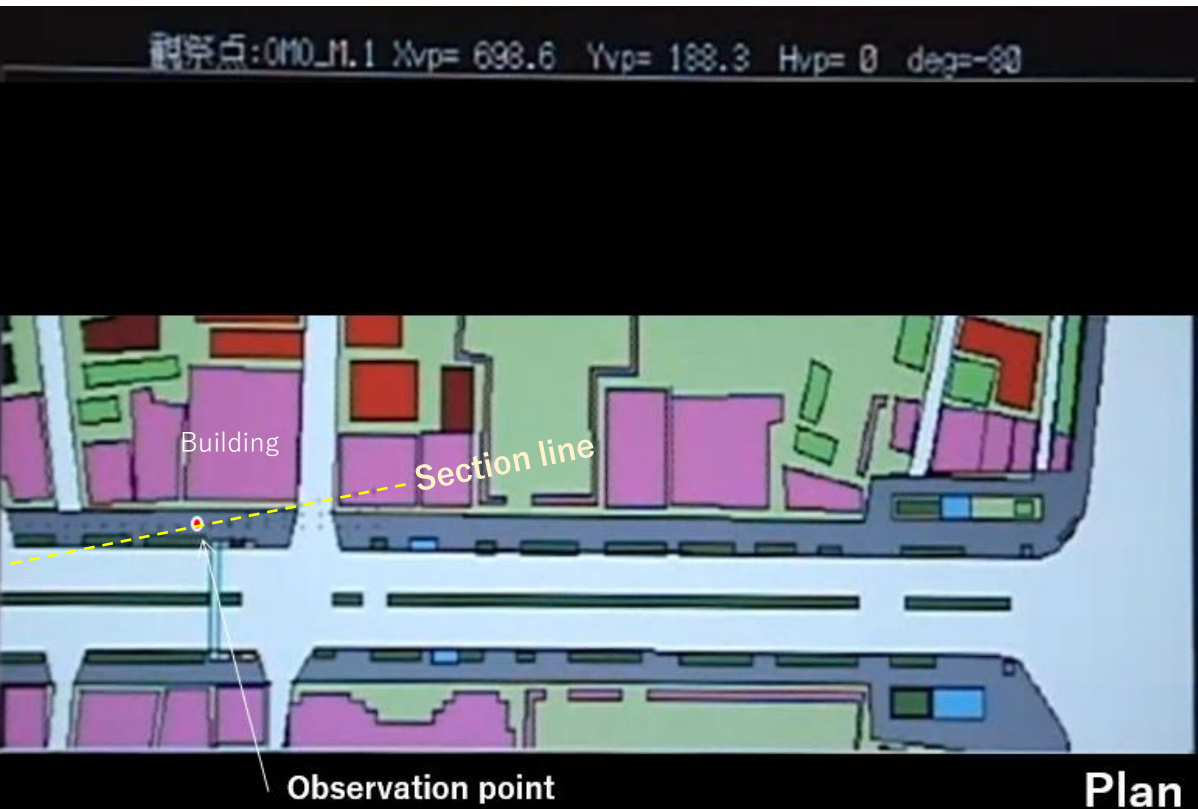

The program:

- Draws a section line through the observation point

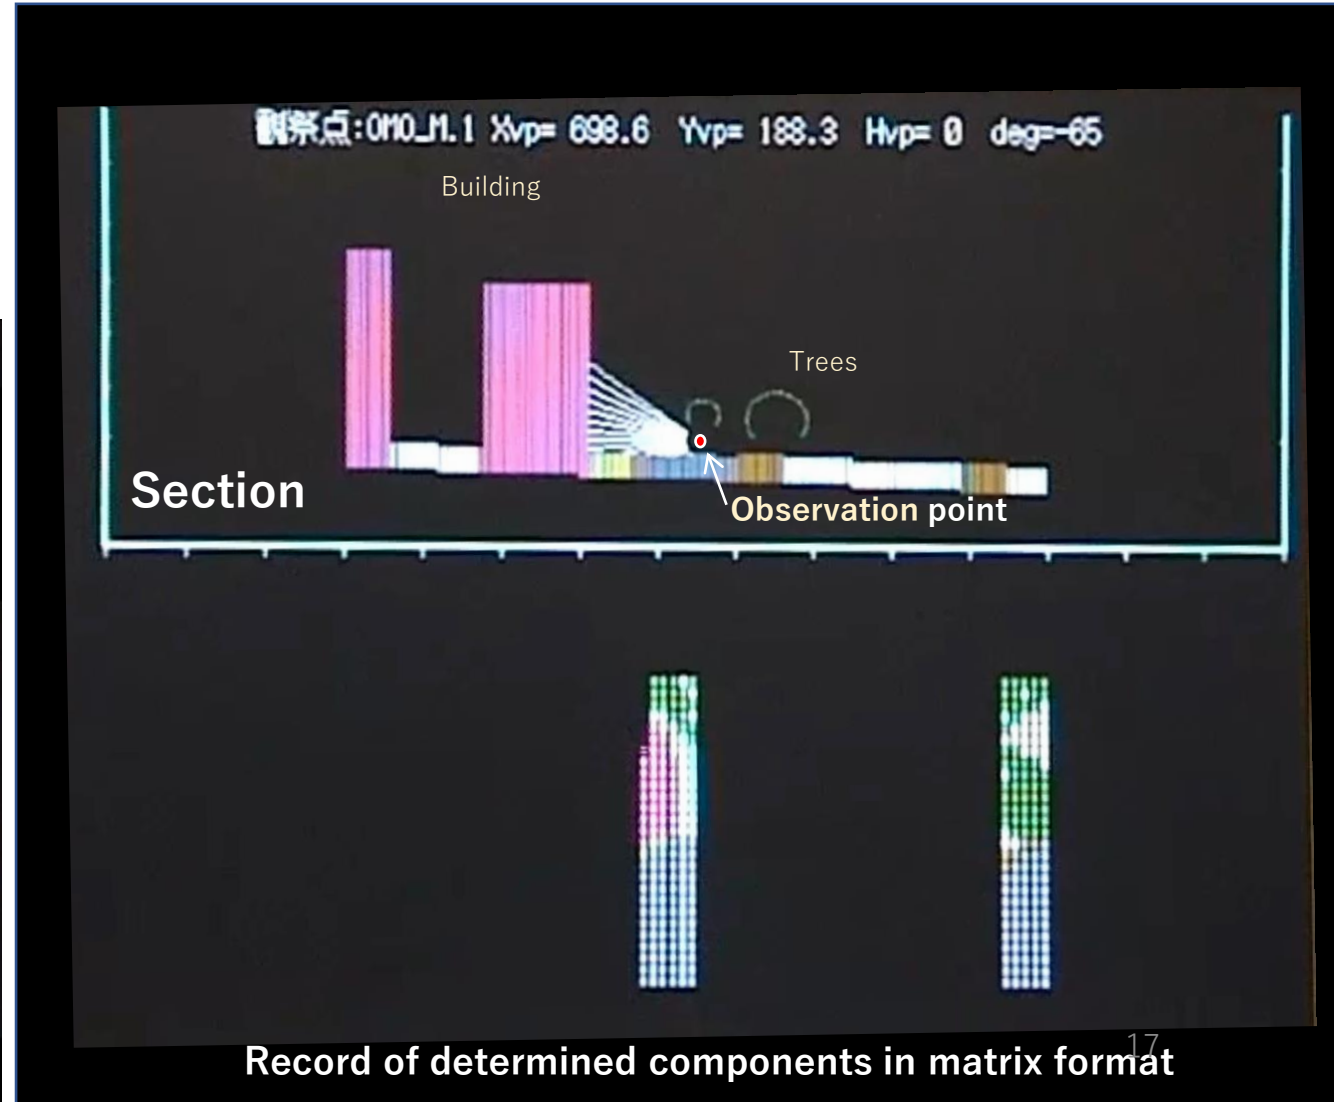

The program in action

- Creates a vertical sectional image
- Emits a scanning line from the observation point
- Determines the component of the surface it strikes
- Records it in the matrix

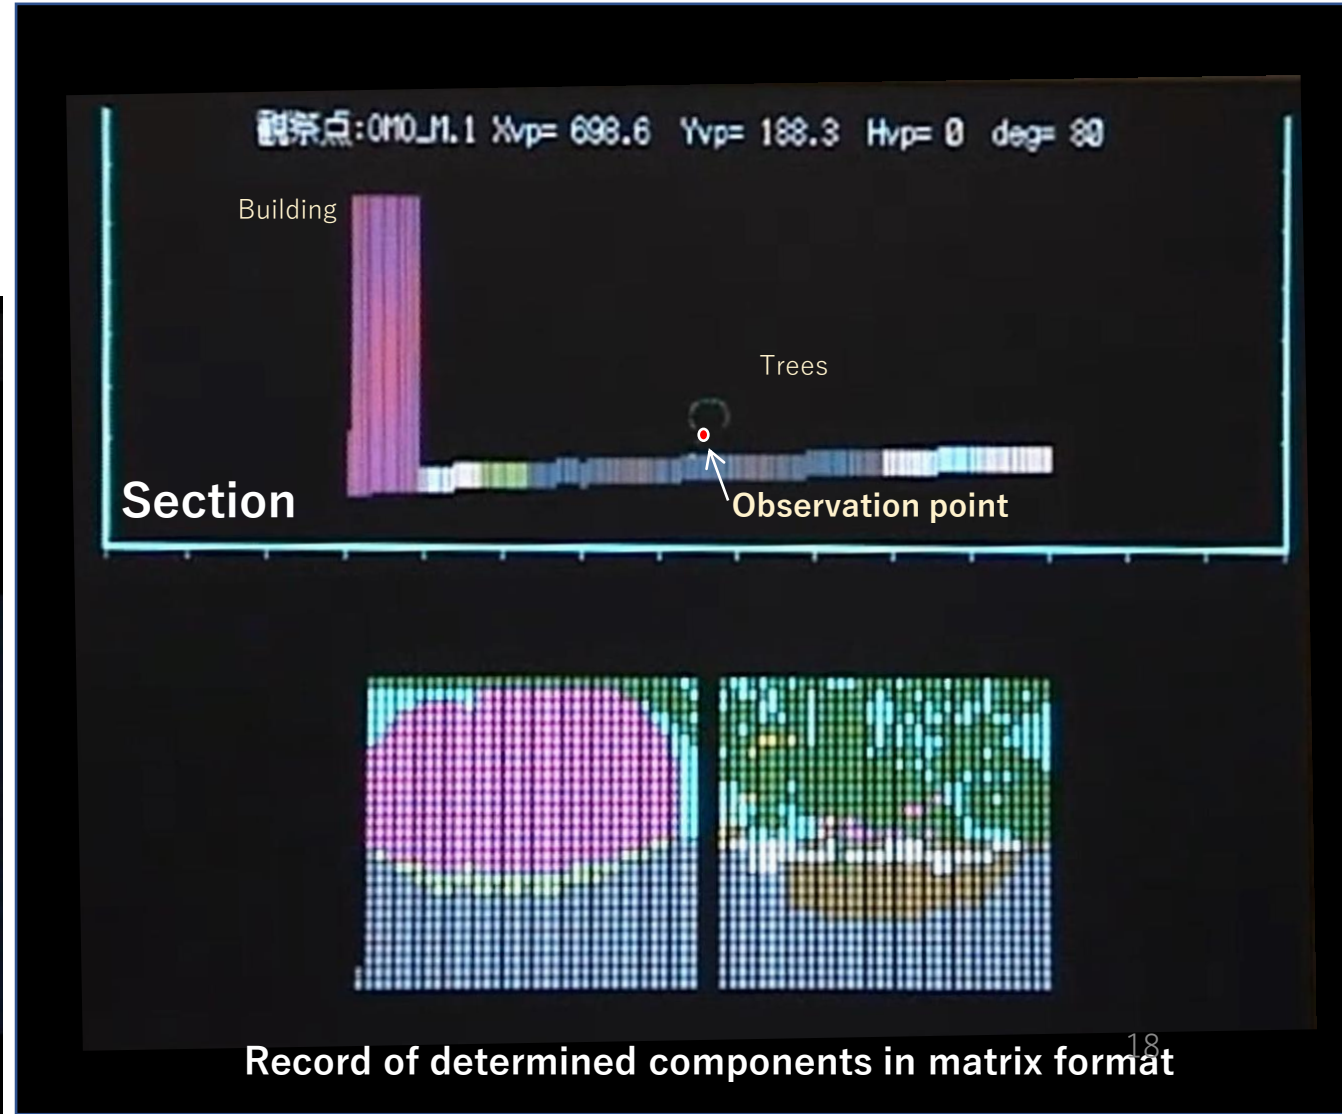

The program in action

Process is repeated after rotating the section line by 5 degrees

The program in action

This results in data taken from all directions

Summation and results

Ratio of visible component

DIRECTION=-90
< COMPONENTS (%) >

ROAD=	2.3
PATH=	34.3
GRASS=	2.2
TREE=1=	20.6
BUILD1=	24.0
HEDGE=	6.0
BRIDG=	0.6
SKY=	10.1

Distance from the observation point

0 - 2.1	m
2.2 - 4.5	m
4.6 - 9.9	m
10 - 21.4	m
21.5 - 48.3	m
48.6 -	m

Distribution map of visible components

Distribution map of line-of-sight length

Study 1:

Describing the sequential experience of an environment using ambient visual data

Sequential experience of a Japanese stroll garden

Method

(a) Terrain data

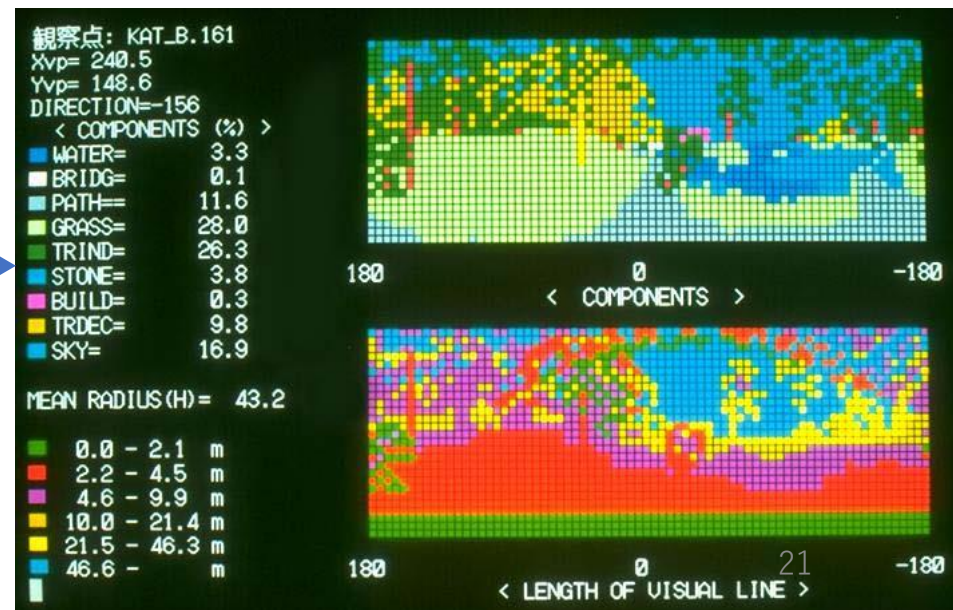

(b) Site plan data

(c) Tree data

(d) Observation point data

Measurement of ambient visual information around the observer

Sequential changes in visual components along the garden path

Measured profiles

Visible components

architecture

evergreen trees

water

Spatial volume

Profiles help account for changes in ambience along the garden path

Study 2:

Influence of ambient visual information on people's behavior in a Japanese stroll garden

Goal: to clarify the relationship between human behavior and ambient visual information in a Japanese stroll garden.

Method

21 participants were asked to walk freely one by one along the garden path while their actions were being recorded with a video camera

Ohno, R., Hata, T., & Kondo, M. (1997). Experiencing Japanese gardens: Sensory information and behavior. In J. Demick et al. (Eds.), *Handbook of Japan-United States environment-behavior research* (pp. 163-182). Plenum Press.

Sorakuen garden, Kobe

Results

Participants' behavior

- Small circles = points where participants stopped along the path
- Thick lines = where they slowed down

Stops and slowdowns for one participant

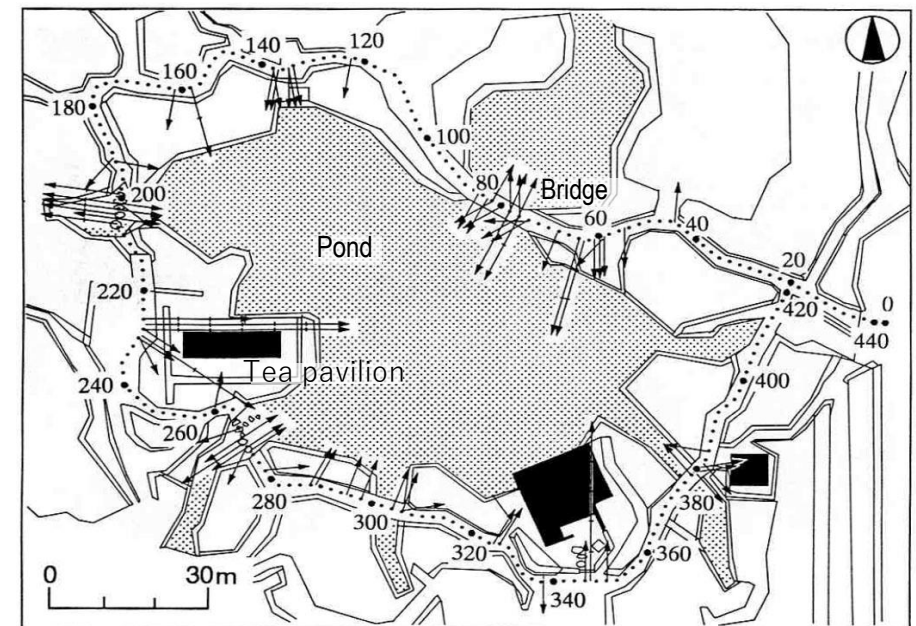

Result 1 :

Participants' behavior

- Participants mostly stopped at the same points
- The arrows on the map indicate the participants' viewing direction.
- Analysis of viewing directions confirms that similar behavior tends to occur in the same places.

A record of all participants' behavior concerning where they slowed down and made a stop.

The stopped points and viewing directions 25

Result 2 :

Ambient visual data

Measured profiles
of the ambient
visual information

Spatial volume

Visible components

Buildings

Water surface

Observation points along the garden path (Number of steps from the starting point)

Analysis and conclusion:

Correspondence between participants' behavior and ambient visual data

- Stops generally corresponded to points where spatial volume and/or visible ratios of buildings and water surfaces increased
- Objective data on ambient visual information can help predict human behavior to some

Stops and slowdowns

Spatial volume

Visible components

Buildings

Water surface

Observation points along the garden path (Number of steps from the starting point)

Summary

- Importance of the nonvisual senses in environmental perception
- Role of kinesthetic memory in place identification
- Concept of ambient vision
- A tool for objectively measuring ambient visual information
- Two studies of Japanese stroll gardens
